Radiosynthesis of [14C]acarbose.

Maul W, Muller L, Pfitzner J, Rauenbusch E, Schutt H.

Pharma Research Center, Bayer AG, Wuppertal, Fed. Rep. of Germany.

Acarbose (O-4,6-dideoxy-4-[[(1S, 4R, 5S, 6S)-4,5,6-trihydroxy-3-(hydroxymethyl)-2-cyclohexen-1-yl]amino]-a-D-glucopyranosyl-(1---- 4)-O-a-D-glucopyranosyl-(1----4)-4-glucopyranose, Bay g 5421), an a-glucosidase inhibitor from Actinoplanes, has been developed for the treatment of diabetes mellitus. To investigate the pharmacokinetics and the biotransformation, 14C-labelled acarbose ([14C]Bay g 5421) was required. About 37 GBq (1 Ci) D-[U-14C]glucose was used as a precursor to obtain [14C]acarbose with a radiochemical yield of between 1.58 and 2.56%. For fermentation purposes resting cells of the Actinoplanes mutant SN 1667/47 were used under cometabolism conditions with a 10-fold excess of maltose. The specific radioactivities achieved in individual preparations were 7.77 MBq/mg (210 microCi/mg), 8.03 MBq/mg (217 microCi/mg), and 9.14 MBq/mg (247 microCi/mg), with a radiochemical purity of greater than 98% in each case. By hydrolysis and subsequent investigation of the hydrolysis products it was shown that [14C]carbon atoms originating from the radioactive glucose are present only in the core and not in the maltose unit of [14C]acarbose.

AB Inhibitors of .alpha.-glucosidases effective against pancreatic .alpha.-amylase and intestinal enzymes such as glucoamylase, sucrase, and maltase were discovered in culture broths of Actinoplanaceae. These inhibitors are oligosaccharides in which an unsatd. cyclitol unit bound to 4,6-dideoxy-4-amino-D-glucopyranose is the integral part in a chain of 1,4-.alpha.-linked D-glucopyranose units. These form a series of homologous compds. with a different no. of glucose units in the mol. Inhibitory activity is strongly dependent on mol. wt. The max. specific inhibitory activity against sucrase in vitro was attributed to **acarbose** (I), which contains 2 glucose units, whereas the strongest .alpha.-amylase inhibitors were of higher mol. wt. In vivo, I not only delays the digestion of sucrose, but is also a very potent inhibitor of starch degrdn. Due to retarded carbohydrate digestion, the postprandial increment of blood glucose and serum insulin in animals and man is dose-dependently reduced by I in loading tests with starch or sucrose. A reduced gain in body wt. in genetically obese Zucker rats fed carbohydrates and I is due to a dose-dependent redn. of food consumption.

AB The action of a new .alpha.-glucosidase inhibitor from **Streptomyces** sp. and **Acarbose** on .alpha.-glucosidases of various origins has been studied. Differences in specificity, efficiency, nature and type of inhibition of microbial glucosidases and some enzymes of the small intestine mucosa by the biol. active substances studied were revealed. It is suggested that the inhibitor from **Streptomyces** sp. (in combination with a diet) can be used for regulation of some disturbances in carbohydrate metab.

AB The acarviosyl transferase of Actinoplanes SE 50/110 is manufd. by expression of the acbD gene encoding it in a suitable expression host. The enzyme catalyzes exchange of the glycosyl moiety of the glycoside with a free sugar and can be used for converting **acarbose** derivs. into **acarbose** or **acarbose** homologs for use in the treatment of diabetes. The enzyme synthesized by Actinoplanes SE 50/110 is secreted into the culture medium from where it can be rapidly purified. The enzyme has a mol. wt. of 76,000, a pH optimum of 6.2-6.9, a temp. optimum of 30.degree. and is active in the range 20-40.degree., and requires calcium. The enzyme uses a wide range of carbohydrates as acceptors (Markush given). Cloning of the acbD gene for the enzyme is also described. The gene was overexpressed in **Streptomyces** lividans using the vector pUWL199-derived plasmid pAS9.

Homology between Streptomyces genes coding for synthesis of different polyketides used to clone antibiotic biosynthetic genes.

Malpartida F, Hallam SE, Kieser HM, Motamedi H, Hutchinson CR, Butler MJ, Sugden DA, Warren M, McKillop C, Bailey CR, et al.

Many important antibiotics such as tetracyclines, erythromycin, adriamycin, monensin, rifamycin and avermectins are polyketides. In their biosynthesis, multifunctional synthases catalyse iterated condensation of thio-esters derived from acetate, propionate or butyrate to yield aliphatic chains of varying length and carrying different alkyl substituents. Subsequent modifications, including aromatic or macrolide ring closure or specific methylations or glycosylations, generate further chemical diversity. It has been suggested that, if different polyketide synthases had a common evolutionary origin, cloned DNA coding for one synthase might be used as a hybridization probe for the isolation of others. We show here that this is indeed possible. Study of a range of such synthase genes and their products should help to elucidate what determines the choice and order of condensation of different residues in polyketide assembly, and might yield, by in vitro recombination or mutagenesis, synthase genes capable of producing novel antibiotics. Moreover, because genes for entire antibiotic pathways are usually clustered in Streptomyces, cloned polyketide synthase genes are valuable in giving access to groups of linked biosynthetic genes.
